The phenomenon of the speed of light slowing down as it goes back in time is known as "theory of relativity," and has puzzled physicists for years. Related Summaries Phenomena that occurred just after the Big Bang may have created the conditions for the formation of the first stars and galaxies, according to the researchers behind an experiment aimed at identifying dark matter, the new predominant form of matter in the universe. Two billion years ago, when the universe was tiny and cool, the equations governing gravity suggested it would have to be ridiculously strong. But the universe was extremely dense, and it's much weaker than theoretically expected. Some physicists wonder whether the universe possesses an extra form of matter to explain the weak gravity. "The production of matter and antimatter has never been observed," says a spokesman for the Tevatron experiment in Chicago. "However, we do know that up to 99% of the energy of the Big Bang was in the form of matter, suggesting that antimatter has to exist." Researchers in the UAE have revealed a new way to produce a type of matter called pure spin - electric charge that spins around in the same direction, and thus behaves differently from conventional charge - by using a "pushing" concept from superstring theories. The process is based on the exchange of particle-antiparticle pairs between the subatomic particles and may lead to the synthesis of pure spin particles that can be used for many f678ea9f9e
